Review

US-20 — Doctor Dashboard Op Dashboard

PARAMETER

DESCRIPTION

Clarity

The title 'Doctor Dashboard Op Dashboard' is duplicative and unclear, and the template with no specific role, function, or purpose is not described. The phrase 'so that the dashboard works as expected' is a placeholder for justification.

Completeness

No acceptance criteria, preconditions, roles, or dashboard widgets/measurements are specified. There is no mention of what 'op dashboard' is (e.g., 'op dashboard?'), what data it displays, or who (doctor, nurse, admin) interacts with it.

Business Value Alignment

No patient safety, compliance, or efficiency outcome is identified. The dashboard is not aligned with clinical decision-making, patient throughput improvement, which are common goals for healthcare dashboards.

Testability

No measurable outcomes, UI elements, or test cases are specified, making it impossible to verify. Examples include no criteria for load testing, role-based access, or error handling.

Technical Feasibility

No dashboard is not described in terms of clinical or operational workflow integration, data occupancy, appointment scheduling, or security. It cannot be assessed against real-world requirements (EHR integration, HL7 data sync, audit control).

Overall Score: 17/100

SUGGESTIONS

How to Reach 100/100

- **Clarity**

Gap: The title is redundant ('Doctor Das' is redundant in the context of the story). The description uses placeholder language ('related functionality works as expected') instead of specific details about the feature or user role.

Fix: Rewrite as a specific story, e.g., 'As a doctor, I want to view a real-time operational dashboard showing patient lab results, and discharge status so that I can make informed decisions.'

- **Completeness**

Gap: No acceptance criteria, precondition, or postcondition are provided. The story lacks detail about the components (e.g., widgets, filters, refresh rate) and the user role.

Fix: Add explicit acceptance criteria such as 'Patient vitals are updated every 5 minutes from the EHR system.' Add a precondition: 'User must be authenticated via hospital network.'

- **Business Value Alignment**

Gap: The story does not articulate any business value (e.g., reduced patient wait time, faster clinician turnover) or compliance driver (HIPAA/Patient Privacy Act).

Fix: Add a value statement like 'so that patient review time is reduced by 20% and ensure compliance with HIPAA results.'

- **Testability**

Gap: There are no measurable success criteria, error/edge cases (e.g., no data available, network outage) for QA to validate.

Fix: Define testable scenarios such as 'Verify patient count within 2 seconds of login.' and 'Verify that unauthorized users cannot access patient-identifiable data.'

- **Technical Feasibility**

Gap: The story does not reference the user interface, RBAC) or performance/compliance requirements. The implementation scope is unclear.

Fix: Specify integration points, e.g., 'Data is pulled from the EHR system via the existing API.'

interface, RBAC) or per-implementation scope un

Fix: Specify integration p
from the hospital EHR sys
PoPIA/HIPAA guidelines.'

AI

Test Cases

1. **Verify authorized doctor Dashboard** (High)

Preconditions: A valid doctor role assigned; user is not currently logged in.

Steps:

1. Navigate to the hospital portal.
2. Enter valid doctor username and password.
3. Click 'Login'.
4. Navigate to/observe the doctor dashboard.

Expected Result: Doctor is redirected to the dashboard, which loads within 3 seconds, displays the doctor's profile, appointment schedule, and available services.

2. **Verify unauthorized role cannot access the Doctor OP Dashboard**

Preconditions: A user account with a role other than Doctor (e.g., Receptionist, Billing).

Steps:

1. Log in using a non-doctor role.
2. Attempt to directly navigate to the Doctor OP Dashboard URL.

2. **Verify unauthorized role (e.g., Billing) cannot access the Doctor OP Dashboard**

Preconditions: A user account exists for a role (e.g., Billing).

Steps:

1. Log in using a non-doctor role (e.g., Billing).
2. Attempt to directly navigate to the Doctor OP Dashboard.

Expected Result: System denies access and displays a 'Insufficient Permissions' message, and the user is redirected to the login screen.

3. **Verify OP Dashboard displays accurate list for the logged-in doctor** (Hypothetical Scenario)

Preconditions: At least 3 outpatient appointments are scheduled in doctor for the current day.

Steps:

1. Log in as the doctor.
2. Open the OP Dashboard.
3. Compare the list of patients/appointments displayed on the dashboard with scheduling/EHR backend data to ensure accuracy.

Expected Result: Dashboard shows accurate list of patients/appointments (name, appointment time, status) matching the backend data, with no missing, duplicated, or stale entries.

4. **Verify system generates an audit log when a doctor views a patient's record from the OP Dashboard**

Preconditions: Audit logging module is enabled on the OP Dashboard.

Steps:

8. **Verify search/filter functionality on patient results** (Medium)

Preconditions: Multiple outpatients are assigned to the doctor on the current day.

Steps:

1. Log in as the doctor and open the patient search interface
2. Enter a valid patient name or ID in the search field
3. Submit the search

Expected Result: Only matching patients are displayed, and the results are accurate and do not expose any patient information outside the doctor's assigned outpatient list.

9. **Verify PHI/sensitive fields are masked in the doctor's specific care-team assignment**

Preconditions: System has multiple doctors, and Patient X is assigned to a care team for Doctor A.

Steps:

1. Log in as Doctor A
2. Navigate to the OP Dashboard and view Patient X (not under Doctor A's own care)

Expected Result: System either excludes Patient X or masks sensitive clinical/PHI fields not necessary for the doctor's role, enforcing minimum-necessary access principles.

10. **Verify dashboard data is transmitted over a secure (HTTPS/TLS) connection** (High)

Preconditions: Access to network traffic analysis tool (Wireshark or proxy).

Steps:
